About the Tutorial

Firebase is a backend platform for building Web, Android and IOS applications. It offers real time database, different APIs, multiple authentication types and hosting platform.

This is an introductory tutorial, which covers the basics of the Firebase platform and explains how to deal with its various components and sub-components.

Audience

This tutorial is directed towards developers in need for a simple, user-friendly backend platform. After you finish this tutorial, you will be familiar with the Firebase Web Platform. You can also use this as a reference in your future development.

This tutorial is intended to make you comfortable in getting started with the Firebase backend platform and its various functions.

Prerequisites

You will need some JavaScript knowledge to be able to follow this tutorial. Knowledge about some backend platform is not necessary, but it could help you to understand the various Firebase concepts.

1. FIREBASE – OVERVIEW

As per official Firebase documentation –

Firebase can power your app's backend, including data storage, user authentication, static hosting, and more. Focus on creating extraordinary user experiences. We will take care of the rest. Build cross-platform native mobile and web apps with our Android, iOS, and JavaScript SDKs. You can also connect Firebase to your existing backend using our server-side libraries or our REST API.

Firebase Features

- **Real-time Database** – Firebase supports JSON data and all users connected to it receive live updates after every change.
- **Authentication** – We can use anonymous, password or different social authentications.
- **Hosting** – The applications can be deployed over secured connection to Firebase servers.

Firebase Advantages

- It is simple and user friendly. No need for complicated configuration.
- The data is real-time, which means that every change will automatically update connected clients.
- Firebase offers simple control dashboard.
- There are a number of useful services to choose.

Firebase Limitations

- Firebase free plan is limited to 50 Connections and 100 MB of storage.

In the next chapter, we will discuss the environment setup of Firebase.

2. FIREBASE – ENVIRONMENT SETUP

In this chapter, we will show you how to add Firebase to the existing application. We will need **NodeJS**. Check the link from the following table, if you do not have it already.

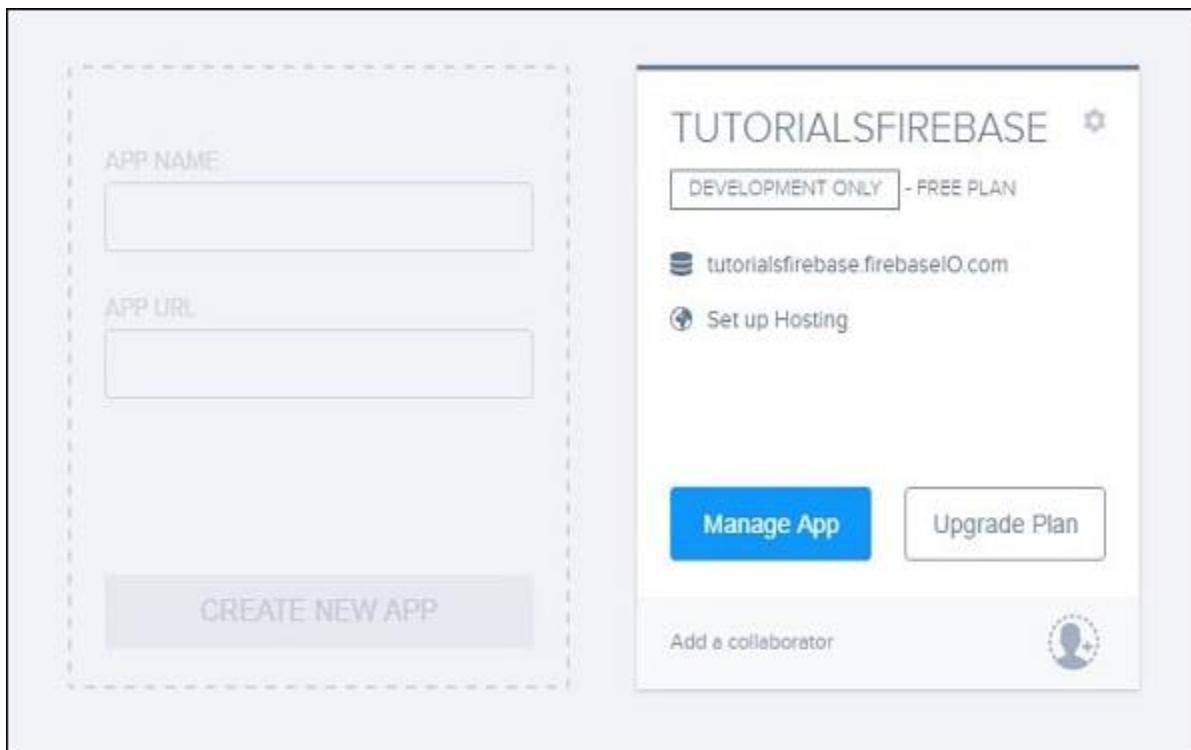

S No.	Software & Description
1	NodeJS and NPM NodeJS is the platform needed for Firebase development. Checkout our NodeJS Environment Setup .

Step 1 – Create a Firebase Account

You can create a Firebase account [here](#).

Step 2 – Create Firebase App

You can create new app from the dashboard page. The following image shows the app we created. We can click the **Manage App** button to enter the app.

Step 3a – Create a basic HTML/JS App

You just need to create a folder where your app will be placed. Inside that folder, we will need **index.html** and **index.js** files. We will add Firebase to the header of our app.

index.html

```
<html>
  <head>
    <script src =
"https://cdn.firebaseio.com/js/client/2.4.2.firebaseio.js"></script>
    <script type = "text/javascript" src = "index.js"></script>
  </head>

  <body>

  </body>

</html>
```

Step 3b - Use NPM or Bower

If you want to use your existing app, you can use Firebase NPM or Bowers packages. Run one of the following command from your apps root folder.

```
npm install firebase --save
```

```
bower install firebase
```

3. FIREBASE – DATA

The Firebase data is representing JSON objects. If you open your app from Firebase dashboard, you can add data manually by clicking on the + sign.

We will create a simple data structure. You can check the image below.

The screenshot shows the Firebase Realtime Database interface. At the top, there are tabs for 'DATA' and 'RULES'. Below the tabs, a URL bar displays the address: <https://tutorialsfirebase.firebaseio.com/>. To the right of the URL bar are three icons: a plus sign (+) for adding new data, a minus sign (-) for deleting data, and a three-dot menu icon. The main area shows a hierarchical database structure under the 'tutorialsfirebase' root. The 'players' node contains two children, '0' and '1'. The '0' child has a 'name' field with the value 'john'. The '1' child has a 'name' field with the value 'amanda'.

In the previous chapter, we connected Firebase to our app. Now, we can log Firebase to the console.

```
console.log(firebase)
```

```
▼ Object {SDK_VERSION: "3.0.5", INTERNAL: Object} ⓘ
  ► INTERNAL: Object
  ► Promise: function Promise()
    SDK_VERSION: "3.0.5"
  ► User: function (a,b,c)
  ► app: function a(a)
    apps: (...)
  ► get apps: function ()
  ► auth: function (c)
  ► database: function (c)
  ► initializeApp: function (a,c)
  ► storage: function (c)
  ► __proto__: Object
> |
```

index.js:1

We can create a reference to our player's collection.

```
var ref = firebase.database().ref('players');

console.log(ref);
```

We can see the following result in the console.

```
▼ U {w: pf, path: L, n: Ae, Oc: false, then: undefined...} ⓘ
  Oc: false
  catch: undefined
  database: (...)
  key: (...)
  ► n: Ae
  parent: (...)
  ▼ path: L
    Z: 0
    ▼ o: Array[1]
      0: "players"
      length: 1
      ► __proto__: Array[0]
    ► __proto__: Object
  ref: (...)
  root: (...)
  then: undefined
  ► w: pf
  ► __proto__: X
> |
```

index.js:3

4. FIREBASE – ARRAYS

This chapter will explain the Firebase representation of arrays. We will use the same data from the previous chapter.

The screenshot shows the Firebase Realtime Database interface. At the top, there are tabs for 'DATA' and 'RULES'. Below the tabs, a URL bar contains the URL <https://tutorialsfirebase.firebaseio.com/>. To the right of the URL are three icons: a plus sign (+), a minus sign (-), and a vertical ellipsis (⋮). The main area displays a JSON tree under the path 'tutorialsfirebase'. The tree structure is as follows:

```
tutorialsfirebase
  players
    0
      name: "john"
    1
      name: "amanda"
```

The data represents an array of objects, where each object has an integer key ('0' and '1') and a 'name' property with values 'john' and 'amanda' respectively.

We could create this data by sending the following JSON tree to the player's collection.

```
['john', 'amanda']
```

This is because Firebase does not support Arrays directly, but it creates a list of objects with integers as key names.

The reason for not using arrays is because Firebase acts as a real time database and if a couple of users were to manipulate arrays at the same time, the result could be problematic since array indexes are constantly changing.

The way Firebase handles it, the keys (indexes) will always stay the same. We could delete **john** and **amanda** would still have the key (index) 1.

Realtime Database

DATA RULES

https://tutorialsfirebase.firebaseio.com/

tutorialsfirebase

players

1

name: "Amanda"

5. FIREBASE – WRITE DATA

In this chapter, we will show you how to save your data to Firebase.

Set

The **set** method will write or replace data on a specified path. Let us create a reference to the player's collection and set two players.

```
var playersRef = firebase.database().ref("players/");

playersRef.set({
  John: {
    number: 1,
    age: 30
  },
  Amanda: {
    number: 2,
    age: 20
  }
});
```

We will see the following result.

The screenshot shows the Firebase Realtime Database interface. At the top, there are tabs for 'DATA' and 'RULES'. Below the tabs, the URL is displayed as <https://tutorialsfirebase.firebaseio.com/>. The main area shows a tree view of data:

```
tutorialsfirebase
  +-- players
      +-- Amanda
          +-- age: 20
          +-- number: 2
      +-- John
          +-- age: 30
          +-- number: 1
```

At the top right of the main area, there are three icons: a plus sign (+), a minus sign (-), and a vertical ellipsis (⋮).

Update

We can update the Firebase data in a similar fashion. Notice how we are using the **players/john** path.

```
var johnRef = firebase.database().ref("players/John");

johnRef.update({
  "number": 10
});
```

When we refresh our app, we can see that the Firebase data is updating.

The screenshot shows the Firebase Realtime Database interface. At the top, there's a blue header bar with the title "Realtime Database" and a help icon. Below the header, there are two tabs: "DATA" (which is selected) and "RULES". Underneath the tabs, there's a URL field containing "https://tutorialsfirebase.firebaseio.com/" and a toolbar with a plus sign, minus sign, and three dots. The main content area displays a hierarchical database structure under the root node "tutorialsfirebase". The "players" node contains two children: "Amanda" and "John". The "Amanda" node has two children: "age" (with value 20) and "number" (with value 2). The "John" node also has two children: "age" (with value 30) and "number" (with value 10).

6. FIREBASE – WRITE LIST DATA

In our last chapter, we showed you how to write data in Firebase. Sometimes you need to have a unique identifier for your data. When you want to create unique identifiers for your data, you need to use the push method instead of the set method.

The Push Method

The **push()** method will create a unique id when the data is pushed. If we want to create our players from the previous chapters with a unique id, we could use the code snippet given below.

```
var ref = new Firebase('https://tutorialsfirebase.firebaseio.com');

var playersRef = ref.child("players");
playersRef.push({
  name: "John",
  number: 1,
  age: 30
});

playersRef.push({
  name: "Amanda",
  number: 2,
  age: 20
});
```

Now our data will look differently. The name will just be a name/value pair like the rest of the properties.

The screenshot shows the Firebase Realtime Database interface. At the top, there's a blue header bar with the title "Realtime Database" and a help icon. Below the header, there are two tabs: "DATA" (which is selected) and "RULES". Under the "DATA" tab, there's a URL field with the value "https://tutorialsfirebase.firebaseio.com/" and three icons: a plus sign, a minus sign, and a three-dot menu. The main content area displays a tree structure of data under the root "tutorialsfirebase". The "players" collection contains two entries, each with a unique key and three data fields: "age", "name", and "number". The first entry has a key of "-KMZ17JP4LKxISS_i1qn" and values: age: 30, name: "John", number: 1. The second entry has a key of "-KMZ17JTecKa_SsfhCiP" and values: age: 20, name: "Amanda", number: 2.

The Key Method

We can get any key from Firebase by using the **key()** method. For example, if we want to get our collection name, we could use the following snippet.

```
var ref = new Firebase('https://tutorialsfirebase.firebaseio.com');

var playersRef = ref.child("players");

var playersKey = playersRef.key();
console.log(playersKey);
```
